*Received 7 November 2005*

**Abstract.** The antisymmetrized molecular dynamics (AMD) simulations suggest that the isospin composition of fragments produced dynamically in multifragmentation reactions is basically governed by the symmetry energy of low-density uniform nuclear matter rather than the symmetry energy for the ground-state finite nuclei. After the statistical secondary decay of the excited fragments, the symmetry energy effect still remains in the fragment isospin composition, though the effect in the isoscaling parameter seems a very delicate problem.

*Keywords:* Multifragmentation, Symmetry energy, Isoscaling
*PACS:* 25.70.Pq

## 1. Introduction

In medium energy heavy-ion collisions, many fragments are formed almost simultaneously in an expanding and excited nuclear system, which gives us an opportunity to investigate the nuclear matter properties at various temperatures and densities, such as the nuclear equation of state and the liquid-gas phase transition. However, fragments are formed in dynamically evolving system in most cases, and therefore dynamical model calculations are necessary.

Antisymmetrized molecular dynamics (AMD) model [ 1, 2, 3, 4, 5] respects several quantum features in fragment formation reactions. It uses a fully antisymmetrized many-body wave function of Gaussian wave packets, which can describe the ground state properties of nuclei reasonably well. The single-particle evolution in the mean field potential is described by the the motion of the wave packet centroids and the stochastic quantum branching process which respects the change of

1219-7580/04/ $ 20.00

the shape of the phase-space distribution, keeping the advantage of the molecular dynamics that the fragments are formed with the wave packets localized in phase space. The two-nucleon collision effect is also treated as a stochastic process.

The AMD simulations for heavy-ion collisions are useful not only to explain the experimental data but also to know what kind of information is reflected in the fragment formation. In Refs. [ 6, 7], we have analyzed the fragment yields in the AMD simulations for multifragmentation reactions of the central collisions of Ca isotopes at 35 MeV/nucleon, in order to see how the fragment isospin composition is related to the symmetry energy term of the effective interaction adopted in the calculation. Isoscaling has been observed in the fragment yield ratios from two reaction systems with different proton-to-neutron ratios in the AMD results as well as in the experimental data [ 9] and in the predictions by various statistical models [ 10] and other dynamical models [ 11, 12, 13]. The symmetry energy has turned out to be reflected in the fragment isospin composition with almost no surface effect, which means that the property of low-density uniform nuclear matter is responsible for the fragment isospin composition rather than the symmetry energy for finite nuclei. The results for the primary fragments are discussed in Sec. 2.

The fragments are recognized in the AMD simulations at a finite time $t \sim 300$ fm/$c$. These primary fragments are excited with the typical excitation energy of about 3 MeV/nucleon and they will decay by emitting particles with a long time scale before they are detected in experiments. In order to compare the calculated results with the experimental data, the secondary decay of primary fragments should be considered by employing a statistical decay code. The effect of the secondary decay on the symmetry energy effects is studied in Sec. 3. Some features observed in the primary fragments remain after the secondary decay, which can be utilized to get the information of the symmetry energy from the experimental data in principle. However, the symmetry energy effect in the isoscaling parameter is produced by a very delicate cancellation of the effect in the width of the isotope distribution and that in the mean isospin asymmetry of fragments.

## 2. Symmetry Energy Effects in Primary Fragments

In this section, we discuss how the density-dependent symmetry energy is reflected in the fragment isospin composition, by using the result of AMD simulations of Refs. [ 6, 7] for ${}^{40}\mathrm{Ca}+{}^{40}\mathrm{Ca}$, ${}^{48}\mathrm{Ca}+{}^{48}\mathrm{Ca}$, and ${}^{60}\mathrm{Ca}+{}^{60}\mathrm{Ca}$. We simulate collisions by boosting two nuclei whose centers are separated by 9 fm and calculating the dynamical evolution of each collision until $t = 300$ fm/$c$. The primary fragments are recognized at $t = 300$ fm/$c$ by the condition that the two nucleons belong to the same fragment if the spatial distance between them is less than 5 fm. The calculations are done with the Gogny force [ 8] and the Gogny-AS force [ 6] which are different in the density dependence of the symmetry energy for nuclear matter as shown in Fig. 1.

We have seen [ 6] that the fragment yield ratios $Y_2(N,Z)/Y_1(N,Z)$ between

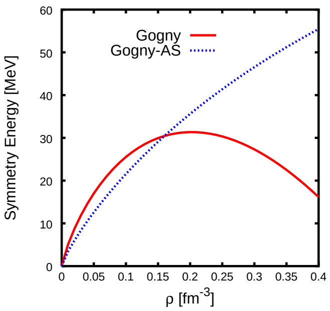

**Fig. 1.** Density dependence of the symmetry energy of nuclear matter for the Gogny force and for the Gogny-AS force.

different reaction systems satisfy isoscaling

$$Y_2(N,Z)/Y_1(N,Z) \propto e^{\alpha N+\beta Z}. \tag{1}$$

Isoscaling is equivalent to the fact that the fragment yields of different reaction systems $i$ are given by

$$Y_i(N,Z) = \exp[-K(N,Z) + \alpha_i N + \beta_i Z + \gamma_i], \tag{2}$$

where $\alpha_i$, $\beta_i$ and $\gamma_i$ are constants that depend on the reaction system $i$, while $K(N,Z)$ is a function that is independent of the reaction system. By combining the fragment yields from the three reaction systems, we can get the function $K(N,Z)$ for a wide region of $(N,Z)$, even though the number of generated events is not very large.

The obtained $K(N,Z)$ behaves very smoothly as a function of $N$ and $Z$ [ 7]. The shell and paring effects are weak in $K(N,Z)$ compared to the effects in the ground state binding energies. We find [ 7] that $K(N,Z)$ can be fitted very well by the functional form

$$K(N,Z) = \xi(Z)N + \eta(Z) + \zeta(Z)\frac{(N-Z)^2}{N+Z} \tag{3}$$

for each $Z$. The quantity $\zeta(Z)$ is related to the width of the isotope distribution for the given $Z$, and it is expected to be sensitive to the symmetry energy.

The top panel of Fig. 2 shows the obtained parameter $\zeta(Z)$ as a function of the fragment proton number $Z$ for the Gogny force and the Gogny-AS force. We find that the $Z$-dependence of $\zeta(Z)$ is very weak for $Z \gtrsim 5$, which is not consistent with the idea of the usual equilibrium of primary fragments. In fact, if the fragments were in thermal and chemical equilibrium, $\zeta(Z)$ would be related to the symmetry energy for the fragment nuclei as $\zeta(Z) = (c_{\mathrm{v}} + c_{\mathrm{s}}A^{-1/3})/T$, where the volume and surface symmetry energy coefficients satisfy $c_{\mathrm{v}} \approx -c_{\mathrm{s}}$ for the ground state nuclei. This size dependence of the symmetry energy is not compatible with the very weak $Z$-dependence of $\zeta(Z)$ for $Z \gtrsim 5$ [ 7].

It may be rather surprising that we can find almost no surface effect even though we are looking at relatively small fragments. There can be several possible explanations [ 7]. One of them is associated with the fact that fragments are not isolated when they are formed. When the density fluctuation is developing from a uniform low density matter, the fragments are still interacting with attractive force through their surfaces. Therefore, the surface free energies can be expected to be smaller for these fragments than for the isolated fragments. Independent of the physical origin for the weakening of the surface symmetry free energy, it suggests that the volume quantity, which is the same as that in the infinite nuclear matter, can be directly obtained by the analysis of the fragmentation results even though the produced fragments are not very large.

If we adopt the interpretation that $\zeta$ is related to the symmetry energy $C_{\mathrm{sym}}(\rho)$ for the uniform matter at a certain density $\rho$ by

$$\zeta = \frac{C_{\mathrm{sym}}(\rho)}{T}, \tag{4}$$

we can utilize the symmetry energy effect observed in the top panel of Fig. 2 to derive $\rho$ and $T$ [ 6]. In order to explain the ratio of $\zeta$ for the Gogny force and the Gogny-AS force which are different in the density dependence of the symmetry energy as shown in Fig. 1, the density should be $\rho \sim \frac{1}{2}\rho_0$. Furthermore, from the absolute values of $\zeta$ and $C_{\mathrm{sym}}(\frac{1}{2}\rho_0)$, the temperature should be $T \sim 3.4$ MeV. This condition of the density and the temperature is reasonable as the condition for the fragment formation, which is necessary for the justification of Eq. (4).

If the fragment yields from different reaction systems satisfy isoscaling, the isoscaling parameter $\alpha$ is related to $\zeta(Z)$ by [ 6, 7]

$$\alpha = 4\zeta(Z) \times \Delta(Z/A)^2, \tag{5}$$

where

$$\Delta(Z/A)^2 = (Z/\bar{A}_1(Z))^2 - (Z/\bar{A}_2(Z))^2 \tag{6}$$

represents the difference of the mean isospin asymmetry of fragments for each given $Z$ between the two reaction systems. We will choose the $^{40}\mathrm{Ca}+{}^{40}\mathrm{Ca}$ system as the system 1 in this paper. Equation (5) can be derived from Eq. (2) by employing Eq. (3), and thus it is not relevant how $\zeta(Z)$ is related to the symmetry energy. It should be noted that $\alpha$ and $\Delta(Z/A)^2$ depend on the reaction systems while $\zeta(Z)$ does not, and that $\zeta(Z)$ and $\Delta(Z/A)^2$ are functions of $Z$ while $\alpha$ should be independent of $Z$.

The middle panel of Fig. 2 shows $\Delta(Z/A)^2$ as a function of $Z$ when the $^{60}\mathrm{Ca}+{}^{60}\mathrm{Ca}$ (and $^{48}\mathrm{Ca}+{}^{48}\mathrm{Ca}$) system is chosen as system 2. The results with the two different symmetry energy terms are shown. The symmetry energy effect is clearly seen in $\Delta(Z/A)^2$ as well as in $\zeta(Z)$, though the effect is in the opposite direction.

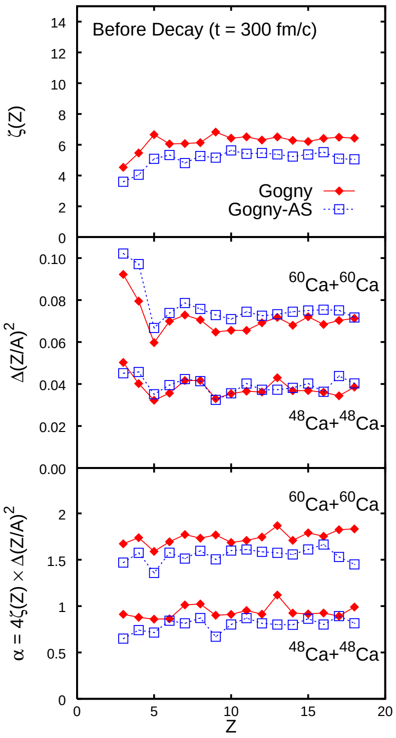

**Fig. 2.** The three quantities $\zeta(Z)$ (top), $\Delta(Z/A)^2$ (middle) and $\alpha$ (bottom) for the primary fragments. The results with the Gogny and Gogny-AS forces are shown by filled diamonds and the open squares, respectively.

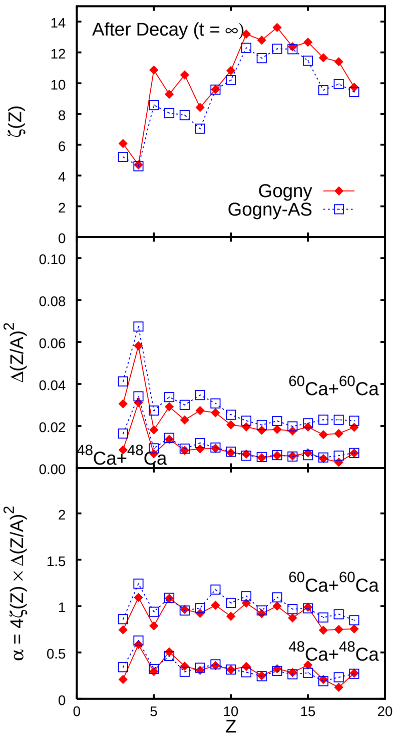

**Fig. 3.** The same as Fig. 3 but for the final fragments.

The bottom panel shows $4\zeta(Z) \times \Delta(Z/A)^2$ which is the product of the top and middle panels and should coincide with the isoscaling parameter $\alpha$. The product is actually almost independent of $Z$, which is consistent with Eq. (5). The symmetry energy effect in $\alpha$ is similar to the effect in $\zeta(Z)$, but it has been produced by the cancellation of the effect in $\zeta(Z)$ and the effect in $\Delta(Z/A)^2$, with the former being larger than the latter.

## 3. Symmetry Energy Effects in Final Fragments

The statistical decay of primary fragments is calculated by using the code [ 14] based on the sequential binary decay model by Pühlhofer [ 15]. The code employed in the present work also takes account of the emission of composite particles not only in their ground states but also in their excited states with the excitation energy $E^* \leq 40$ MeV. The experimental information is incorporated for known levels of $A \lesssim 28$ nuclei, while the Fermi-gas level density is assumed otherwise with the level density parameter $a = A/(8 \text{ MeV})$.

For the final fragments after the statistical decay, the quantities $\zeta(Z)$ and $\Delta(Z/A)^2$ can be defined in the same way as for the primary fragments. Equation (5) holds for the final fragments as well if isoscaling is good and Eq. (3) is approximately valid for the final fragments. However, $\zeta(Z)$ for the final fragments is not necessarily related to the symmetry energy directly in a simple way.

The top and middle panels of Fig. 3 show $\zeta(Z)$ and $\Delta(Z/A)^2$, respectively, calculated for the final fragments. The absolute values of $\zeta(Z)$ and $\Delta(Z/A)^2$ change from those in Fig. 2 for the primary fragments. Nevertheless, the effect of the symmetry energy term in $\zeta(Z)$ and $\Delta(Z/A)^2$ is similar to what we have observed for the primary fragments. This means that the symmetry energy effect in the dynamical stage of the reaction is observable in principle even after the secondary decay of fragments.

However, in the isoscaling parameter $\alpha$ which is shown as $4\zeta(Z) \times \Delta(Z/A)^2$ in the bottom panel of Fig. 3, the symmetry energy effect is not clearly seen. This is because the symmetry energy effect in $\zeta(Z)$ is largely canceled by that in $\Delta(Z/A)^2$ to give this small effect in $\alpha$. We expect that the situation of such cancellation may be sensitive to the details of the statistical decay code, and therefore it is not easy to predict the symmetry energy effect in $\alpha$ for the final fragments at the current stage.

## 4. Summary

The isospin composition of fragments produced by the AMD simulations is analyzed to see how the symmetry energy is reflected. The studied quantities $\zeta(Z)$, $\Delta(Z/A)^2$ and $\alpha$ for the primary fragments are sensitive to the symmetry energy term in the effective interaction, and the calculated results suggests that the symmetry energy of uniform nuclear matter at a reduced density $\rho \sim \frac{1}{2}\rho_0$ is directly responsible for the isospin composition of the primary fragments even though the fragments are of finite size. A statistical decay calculation shows that the symmetry energy effects in $\zeta(Z)$ and $\Delta(Z/A)^2$ remain after the secondary decay of the primary fragments. However, the symmetry energy effect in $\alpha$ for the final fragments requires a careful study because it is given by a delicate cancellation of the effect in $\zeta(Z)$ and the effect in $\Delta(Z/A)^2$.

## Acknowledgments

The main part of this talk was based on the collaboration with M. B. Tsang, W. G. Lynch, P. Danielewicz and W. A. Friedman, which was supported by Japan Society for the Promotions of Science and the US National Science Foundation under the U.S.-Japan Cooperative Science Program (INT-0124186), by the High Energy Accelerator Research Organization (KEK) as the Supercomputer Project, and by grants from the US National Science Foundation, PHY-0245009, PHY-0070161 and PHY-01-10253, and a Grant-in-Aid for Scientific Research from the Japan Ministry of Education, Science and Culture. The work was also partially supported by RIKEN as a nuclear theory project.
